MEMORANDUM

TO: Robert S. Kier  
FROM: Tony R. St. Clair  
PROJECT: REM II - EPA Contract No.: 68-01-6939  
SUBJECT: South Cavalcade Drilling Evaluation  
DOCUMENT  
NUMBER: 143-TS1-IO-BVAT-1  
DATE: October 21, 1985

On October 10 and 11, 1985, I was in Houston to observe a test drilling program conducted by McBride-Ratcliff and Associates, Inc. (MRA). The test was to be performed in order to determine which method, mud-rotary or hollow stem, would be better suited for monitor well installation and subsurface sampling at the South Cavalcade site. Two drilling contractors were used for the test; Vann and Sons, Inc. for the mud-rotary method, and Custom Coring, Inc. for the hollow stem method.

On the first day, Vann and Sons, Inc. set up their truck mounted mud-rotary rig on the esplanade between the eastbound and westbound lanes of Cavalcade Street. Those present to witness the drilling, in addition to myself and the drilling team, were: (1) Bill Tobin, MRA, (2) Paul Moore, MRA, and (3) John Cochran, EPA. The driller's plan was to begin their sampling using a standard Shelby tube with a 24-inch push and then, after setting a surface casing, to begin water circulation. After successful sampling of the clay in the five to ten foot region it was decided that, because of the high clay content and proximity of the sand layer, the water circulation was not needed. This decision was based on a old drilling log which showed a single sand layer at about 15 feet. The drillers and MRA decided that a steel casing extended to seal off the sand layer should suffice. This worked well until other sand layers were found beneath the first so more casing had to be continually added. This caused a problem in that there were so many collar fittings on the casing that it was difficult to insert and remove the casing. The casing was finally set at 33 feet and clay was sampled to 50 feet.

While this method was relatively fast, there were problems associated with driving the casing at the deeper levels. No major problems were encountered while sampling with either the Shelby tube or the split-

Page 2

spoon samplers. Recovery on nearly all samples was high and it was fairly easy to determine at what levels the stratigraphy changed. This method is essentially the same as hollow stem augering except that the casing is advanced only far enough to seal off the lowest sands; while this may be satisfactory for sampling, it could have limitations for well installations.

On the second day, Custom Coring, Inc. came to try hollow stem augering at nearly the same spot as the day before. Bill Tobin and John Cochran were not present this day. Custom Coring's rig was mounted on a "mud buggy" and, while tremendously oversized for this job, would perform well in muddy areas or locations where access with a small tired vehicle would be limited. This team used a thin-walled Acker tube for sampling the clay and in several cases the tubes were ruined because they could not stand up to the pressure of being forced into the stiff clay. Samples were easy to take with their rig setup but they once had a problem of extracting the sampler from the ground.

This method took considerably longer to do the job and, because of the bulk of the five-foot auger flights, was more strenuous. Recovery was about the same as with other methods and no major problems were encountered.

Both methods provided samples of about the same quality but for well installation the hollow stem is preferred. However, since the mud-rotary technique was never used the true objective of the test was not accomplished.

I also have for your information a copy of the drilling logs and a pictorial summary of the work that was performed during these two days.

## Guide to Photographs

- Photo 1. - Vann and Sons, Inc. drilling rig on esplanade.
- Photo 2. - First sample taken using the Shelby tube.
- Photo 3. - Clay sample being removed from tube using hydraulic extruder.
- Photo 4. - Clay sample taken at eight to ten feet.
- Photo 5. - Steel casing being pushed into place.
- Photo 6. - Sample taken at 33 to 35 feet (end of casing).
- Photo 7. - Custom Coring, Inc. drilling rig on esplanade.
- Photo 8. - Mast raised and ready for sampling.
- Photo 9. - First sample taken using the Acker tube.
- Photo 10. - This tube has been ruined by being forced into the clay.
- Photo 11. - Advancing the continuous flight.
- Photo 12. - Sand sample taken with a split-spoon at 14 to 16 feet.
- Photo 13. - Last sample being removed at 45 feet.
